Abstract

Introduction: Annual incidence rates for oral and pharyngeal cancer are estimated at 25 cases per 100,000 in developing countries. Human papilloma virus (HPV) was implicated in pathogenesis of Cancer. The mutations of p53 and c-myc are found 50% in cancer. Objective: Aims of this research were to know the incidence of OSSC patient which realized HPV infection without p53 and c-myc gene mutation. Materials and Methods: Tissue biopsy frozen sections were taken from BOSC (Benign Oral Squamous Cell) and OSCC (Oral Squamous Cell Carcinoma) patients collected from Oral and Dental Departement of dr Muwardi Distric Hospital in Surakarta from January 2007 to January 2008. To amplify L1-HPV gene for fixed the HPV stressor. To amplify p53 and c-myc genes, continued with SSCP (Single Strand Conformational Polymorphisme) analysis and followed with measurement using densitometer, to see mutation existence. The collected data were analyzed with Chi Square. Results: BOSC patient identified 23% with HPV infections and OSCC patient identified 73% with HPV infections. Hundred percent BOSC patient with HPV infection without mutation in p53 gene and c-myc gene, 81% OSCC patient with HPV infection without mutation in p53 gene and 91% OSCC patient with HPV infection without mutation in c-myc gene. Chi Square analysis showed significant difference between BOSC and OSCC patients with HPV infection without mutation in p53 and c-myc gene. Conclusion: HPV is a factor for pathogenesis of OSCC.

Keywords: Developing countries; HPV; Pathogenesis; OSCC
Introduction

Update research found that cancer is widely perceived as a heterogeneous group of disorders with different biological properties, are caused by a series of clonally selected genetic changes in tumour-suppressor genes and oncogenes. However, recent data suggest that cancer has a common basis that is grounded in a polyclonal epigenetic disruption of progenitor cells, mediated by tumour-progenitor genes. Tumour cell heterogeneity is due in part to epigenetic variation in progenitor cells and epigenetic plasticity together with genetic lesions drives tumour progression. This crucial early role for epigenetic alterations in cancer is in addition to epigenetic alterations that can substitute for genetic variation later in tumour progression. Therefore, non-neoplastic but epigenetically disrupted might be a crucial target for cancer risk management.

Cause of cancer can divide into two groups: environmental cause and hereditary genetic cause. Cancer is primarily an environmental disease, though genetics influence the risk of some cancers. Environmental factors include: environmental pollutants, diet and obesity, tobacco, infections, radiation, and lack of physical activity. These environmental factors cause or enhance abnormalities in the genetic of cells. The prevalence of oral cancer is increase in Africa. Annual incidence rates for oral and pharyngeal cancer are at 25 cases per 100,000 in developing countries. The urbanisation and increasing access to, and utilisation of tobacco in its various forms and edentulism. Another researcher found that human papilloma virus (HPV), implicated in Oral Squamous Cell Carcinoma (OSCC) pathogenesis. Therefore, non-neoplastic but epigenetically disrupted might be a crucial target for cancer risk management.

HPV with p53 proteins lead to decrease the apoptosis. The other hand binding of E7 proteins with pRb protein lead to activate c-myc protein expression so be impact in decreases the proliferation. The mutations of p53 and c-myc are not found. This concept gives a chance to explain the increasing OSCC.

In the disease of high risk HPV infection explained the viral genome integrates into the host genome which is the necessary event for the keratinocytes immortality. During this process of integration the circular form of viral genome breaks at the level of the E1 and E2 regions. Different studies have shown that the integrated part of the genome corresponds to E1, E6 and E7. The loss of E2 during this process of integration produces the loss of E6 and E7 control. Therefore, the sequences E6 and E7 are directly involved in the cellular cycle by inhibiting the normal functions of p53 and pRb. The p53 can provoke the arrest of cellular division and assure the time necessary for DNA repair. If damage can’t be repaired, p53 is able to induce the apoptosis and prevent the propagation of DNA damage in subsequent generations of cells. In the case of other types of tumours, p53 is usually mutated and acts as a real oncogene. In the case of HPV infection, E6 suppresses the properties of p53 gene product achieving the functional equivalent of the two hits required to knock out both alleles of a tumour suppressor gene. The mutations of p53 are normally not found. The E7 protein interacts with retinoblastoma protein (pRb), which is the crucial factor for the cellular cycle control. This interaction causes the release of the transcription factor E2F, which is now free to act and can stimulate the cellular division. E6 and E7 can cooperate with cellular oncoproteins like ras and myc which enables the virus to act at the level of growth factors and cellular and nuclear metabolism producing oncogenic cells. E6 and E7 can provoke directly DNA mutations of the host cell. This means that certain types of HPV are able to cause malignant lesions even without the action of other cofactors.

Materials and Methods

Foutry frozen section BOSC tissue and fifteen frozen section OSCC tissue patients collected from Oral and Dental Clinic of dr Muwardi Distric Hospital in Surakarta from January 2007 to January 2008. Parrafin blocks were made from cutting I, which was subsequently stains with Haematoxyline Eosine (HE) to ascertain the type of neoplasm.

Cutting II was subjected to Deoxyribonucleic Acid (DNA) isolation was made by Henk Schmits method with some modifications. Cut up to 25 mgr of tissue into small pieces, place in 1.5 ml a microfuge tube volume, and add 200 ul of DNA extraction buffer. Add 20 ul of Proteinase
K stock solution, mix by vortexing, and incubate at 55°C overnight.14

The DNA isolation results were subjected to Polymerase Chains Reaction (PCR) to amplify L1-HPV for fixed the HPV stressor. Diagnose related HPV infections are made by Henk Schmits and/or Nigel McMillan and Nina Fowler PCR-method with some modifications.14,15 Twenty five µl microfuge tube Ready To Go PCR Bead (Amersham Pharmacia Biotech) mixed with 2 µl HPV consensus primers (MY09: 5’GC(A/C)CAGGG(A/T)CATAA(G/C)ATTGC3’ and MY11: 5’CGTCC(A/C)A(A/G)(A/G)GGA(G/A)(C/T)ACTATC3’) (CYBERGENE AB) and 2 µl DNA template. PCR protocol for both amplifications are 94°C for 50 seconds, 59°C for 50 seconds, 72°C for 50 seconds and 4°C soak. The Amplification of HPV-L-1 gene produced 450 bp long.

Other DNA isolation results were subjected to Polymerase Chains Reaction (PCR) to amplify p53 and c-myc gene and continued Single Strand Conformational Polymorphism (SSCP) analysis and followed with measurement using densitometer to see mutation existence. To amplify of p53 and c-myc made by Henk Schmits and/or Nigel McMillan and Nina Fowler PCR-method with some modifications.14,15 Twenty five µl microfuge tube Ready To Go PCR Bead (Amersham Pharmacia Biotech) mixed with 2 µl p53 primer (forward primer 5’TATCCTGAGTAGTGGTAA TC3’ and backward primer 3’AAGTGAATCTGAGGCATAAC’) (Cybergene AB) and 2 µl sample DNA (template). The other hand twenty five µl microfuge tube Ready To Go PCR Bead (Amersham Pharmacia Biotech) mixed with 2 µl c-myc primer (forward primer 5’CCGTCCCTGGCTCCCCTCCTG3’ and backward primer 3’GTATCGTCGCCCGCCCGTTGAAAC5’) (Cybergene AB) and 2 µl sample DNA (template). PCR protocol for both amplifications are 94°C for 50 seconds, 59°C for 50 seconds, 72°C for 50 seconds and 4°C soak. The Amplification of p53 gene produced 216 bp and c-myc gene produced 347 bp. Single Strand Conformational Polymorphism (SSCP) analysis followed with measurement using densitometer (Shimadzu CS 930, Dual Wave Length Cromato Scanner) to see mutation existence.

Results

The result of this research showed that nine patient from 40 patient BOSC identified have HPV infections (9/40 = 23%). Eleven patient from 15 patient OSCC identified have HPV infections (11/15 = 73%) (Figure 1)

Another result of this research showed that nine patient without mutation in p53 gene (9/9 = 100%) and 9 patient without mutation in c-myc gene (9/9 = 100%) after SSCP analysis that confirm by densitometer against nine patient BOSC with HPV infection. The other hand, nine patient without mutation in p53 gene (9/11 = 81%) and 10 patient without mutation in c-myc gene (10/11 = 91%) after SSCP analysis that confirm by densitometer against eleven patient OSCC with HPV infection (Figure 2A, 2B, 2C and Figure 3A, 3B, 3C)

**Discussion**

Dental caries and periodontal disease are generally considered to be the major oral health problems around the world. In developing countries of Africa, these appear to be neither as common nor of the same order of severity as in the developed world. An epidemiological description of a given health problem usually includes its prevalence, severity (morbidity, mortality) and age-adjusted distribution in the population. Oral diseases known to exist in each community must be assessed in this way in order to develop programmes appropriate to community needs. Based on this form of analysis, the most prominent oral health problems in Africa amongst low socio-economic communities include Noma, ANUG (Acute Necrotising Ulcerative Gingivitis), oral cancer, the oral manifestations of HIV and AIDS, orofacial trauma, and dental caries. Studies have shown that the oral manifestations of HIV/AIDS are common. Candida infections, necrotizing gingivitis and oral hairy leukoplakia are the most common. The prevalence of oral cancer is also on the increase in Africa. Annual incidence rates for oral and pharyngeal cancer are estimated at 25 cases per 100,000 in developing countries. The rapid urbanisation and increasing access to, and utilisation of tobacco in its various forms as well as alcohol, is leading to. So the main risk factors are tobacco abuse, smokers represent 90% of oral cancer patients. Other risks that under research are viral infection like HSV and HPV. P53 is a gene that codes for a protein that regulates the cell cycle and hence functions as tumor suppression. It is very important for cells in multicellular organisms to suppress cancer. P53 has been described as the guardian of the genome, referring to its role in conserving stability by preventing genome mutation. The name is due to its molecular mass: it is in the 53 kilodalton fraction of cell proteins. The human p53 gene is located on the seventeenth chromosome (17p13.1). It plays an important role in cell cycle control and apoptosis. Defective p53
could allow abnormal cells to proliferate, resulting in cancer. As many as 50% of all human tumors contain p53 mutants.18 And c-myc codes for a protein that binds to the DNA of other genes and is therefore a transcription factor. When a gene like myc is altered to cause cancer, the cancerous version of the gene is called an oncogene. The healthy version of the gene that is derived from is called a proto-oncogene. Myc gene is located on chromosome 8 in humans and encodes for a transcription factor that is believed to regulate expression of 15% of all genes.19,20 This means that in addition to its role as a classical transcription factor, Myc also regulate global chromatin structure by regulating histone acetylation both in gene-rich regions and at sites far from any known gene.21

Conclusion

Virus Human papilloma (HPV) is a factor for pathogenesis of Oral Squamous Cell Carcinoma (OSCC).
